

# Persistence

SWE 432, Fall 2017

Design and Implementation of Software for the Web

# Today

- Demo: Promises and Timers
- What is “state” in a web application?
- How do we store it, and how do we choose where to store it?

# Demo: Promises and Timers

What is “state” in a  
web app?

# Application State

- All data in an application
- What kinds of data are we concerned about?
  - What user is logged in?
  - What interactions have they had with us before?
  - What data have they given us?
  - What data have others given us?
- Where do we store all of these things?

# State: Example

Amazon.com...

Home page

Login

Browse

Add to cart

visit  
[amazon.com](https://www.amazon.com)

A screenshot of the Amazon.com homepage. The browser title bar shows "Amazon.com: Online Shopping" and the URL "https://www.amazon.com". The page itself is a dark-themed version of the homepage. At the top, there are promotional banners for "NEW & INTERESTING FINDS ON AMAZON" and "EXPLORER". The main navigation bar includes links for "Amazon Prime", "All", "Search", "GAME CHANGER", "Help support kids in", "Departments", "Browsing History", "Jonathan's Amazon.com", "Hello, Jonathan", "Your Account", "Prime", "Lists", and a shopping cart icon with a "1" notification. The main content area features a large advertisement for the "ALL-NEW fire TV stick with Alexa Voice Remote" priced at "\$39.99". Below this, there is a promotional offer: "GET UP TO \$65" and "OF DIGITAL CONTENT WHEN YOU ACTIVATE". The overall layout is clean and modern, typical of the Amazon website.

# HTTP is stateless

- Each request / response pair is independent of previous request / response pair
- Frontend cannot assume that it is making request to the same server.
  - Might be load balanced, crash, ...

# Where to persist application state?

- Many options
- Goals:
  - Cost
  - Efficiency
  - Stability

Web “Front End”

Our Node Backend

Storage provider

# Where to persist application state?

- Should consider how often we need to show it to the user, and how permanently we need to store it
- Examples:
  - What user is logged in? (Transient, relevant to user and backend)
  - What's in my shopping cart? (Semi-transient, relevant to user and backend)
  - What products am I looking at? (Transient, relevant to user)
  - What are all of the products (Long-term, parts are relevant to users)

Frontend  
(browser)

Backend  
(webserver)

Storage  
provider

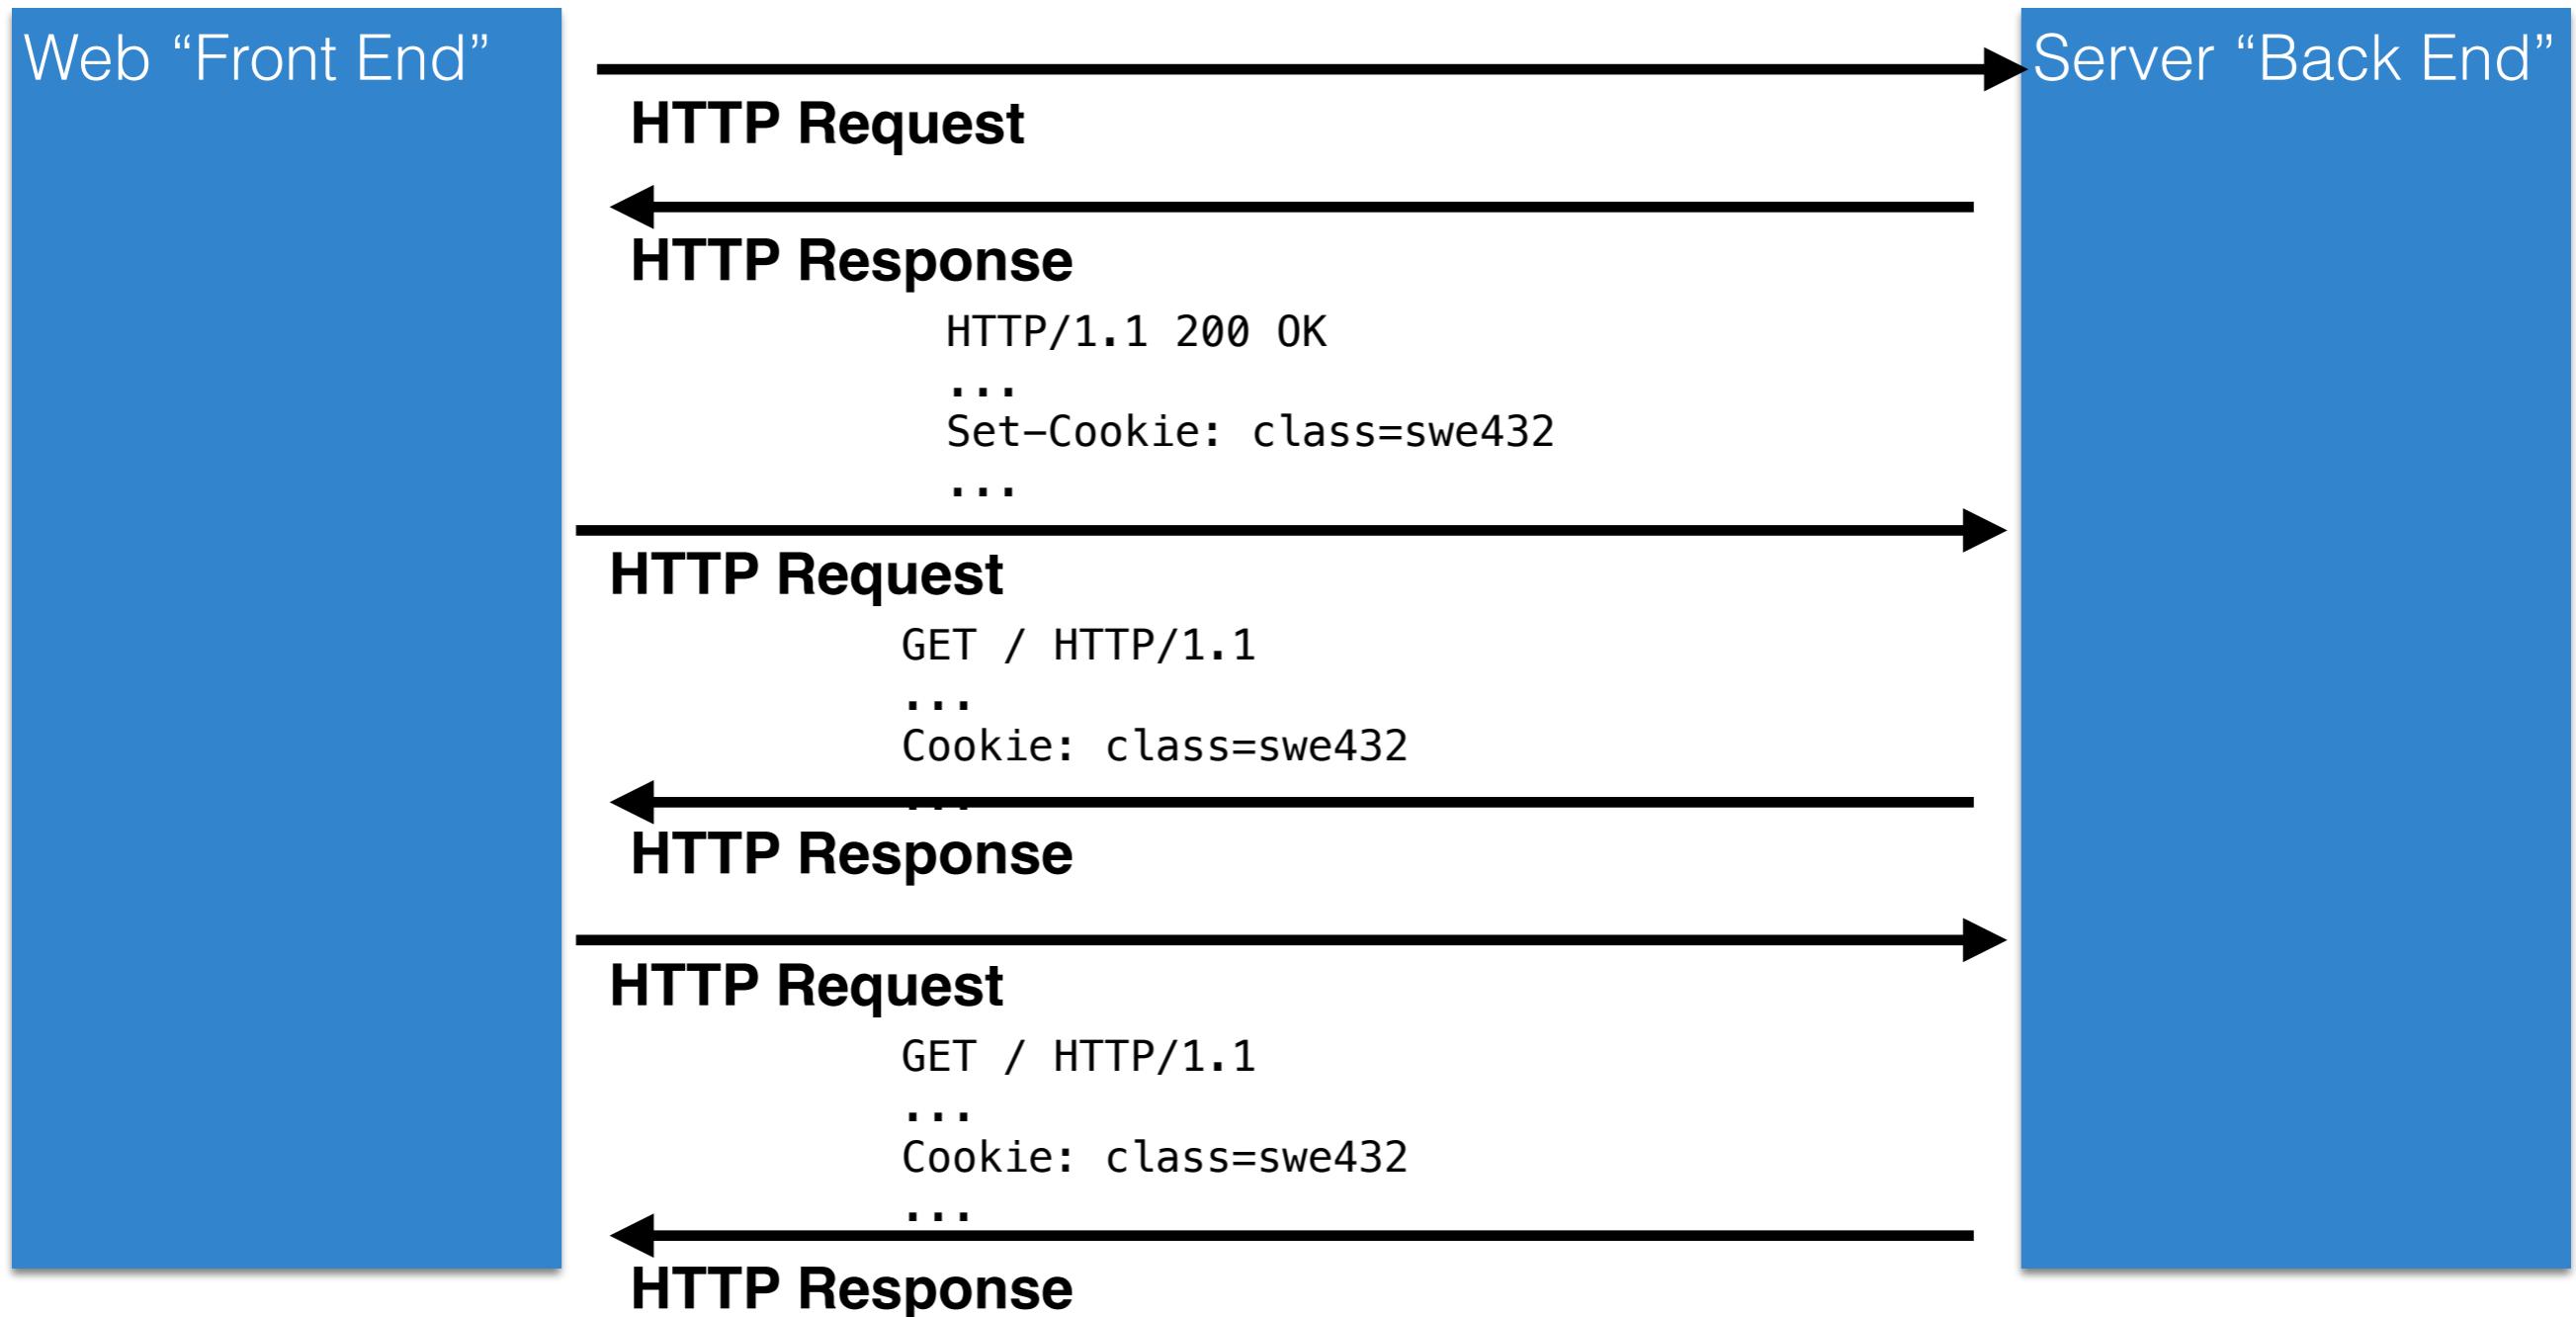

# Where to persist application state

- URL and query parameters
  - Really small amounts of data
  - Data that should be changed through forward/back buttons in browser
- Frontend
  - Data we might need to show again soon
  - Fairly small (KB's or few MBs, not 100 MB's or GB's)
  - Data we don't care about going away or being maliciously manipulated
- In memory on backend
  - Data that we are working with that will fit in memory (MB's probably not GB's)
  - Transient data that can disappear if the server crashes
  - Cache or index of data stored on backend disk, database, or storage provider
- On backend disk or database
  - Data we need persisted "permanently"
  - Data that only needs to be used by single server
- Storage provider
  - Data we need persisted "permanently"
  - Data that we need to share across multiple servers

# Frontend State: Cookies

- String associated with a name/domain/path, stored at the browser
- Series of name-value pairs, interpreted by the web application
- Create in HTTP response with “*Set-Cookie:* ”
- In all subsequent requests to this site, until cookie’s expiration, the client sends the HTTP header “*Cookie:* ”
- Often have an expiration (otherwise expire when browser closed)
- Various technical, privacy and security issues
  - Inconsistent state after using “back” button, third-party cookies, cross-site scripting, ...

# Cookies and Requests

# Cookies & NodeJS

- cookie-parser enables reading and writing cookies
  - npm install cookie-parser
  - let cookieParser = require('cookie-parser');
- Stateful Hello World

```
const express = require('express');
const cookieParser = require('cookie-parser');
const app = express();

app.use(cookieParser());

app.get('/', (req, res) => {
  if(req.cookies.helloSent == "true")
    res.send("I already said hello to you!");
  else
    res.cookie("helloSent","true").send('Hello World!');
});

app.listen(3000);
```

# Persisting more complex state

- The most cookies you can have: 4KB (TOTAL per DOMAIN)
- Old solution
  - Cookie is a key to some data stored on server
  - When client makes a request, server always includes this “extra data” being stored on server
- What’s wrong with this old solution?
  - Really slow
  - For every request
    - Client passes key to server using cookie
    - Server loads data corresponding to key
    - Client downloads data as part of HTTP response

# Frontend State with LocalStorage

- HTML5 added support for persisting larger data on the frontend

**localStorage** (Persists forever)

**sessionStorage** (Persists until tab is closed)

- To use localStorage and sessionStorage

```
setItem("key", "value");
getItem("key");
```

```
var id = localStorage.getItem("userID");
```

- Can store any string
- All pages in the same domain see the same localStorage and sessionStorage
- Alternatively: SQLite (SQL DB) that you can use in JS

Persisting state on the  
backend

# Storing state in a global variable

- **Global variables**

```
var express = require('express');
var app = express();
var port = process.env.port || 3000;

var counter = 0;
app.get('/', function (req, res) {
  res.send('Hello World has been said ' + counter + ' times!');
  counter++;
});

app.listen(port, function () {
  console.log('Example app listening on port ' + port);
});
```

- Pros/cons?
  - Keep data between requests
  - **Goes away** when your server stops
  - Should use for transient state or as cache

# What forms of data might you have

- Key / value pairs
- JSON objects
- Tabular arrays of data
- Files

# Options for backend persistence

- Where it is stored
  - On your server or another server you own
    - SQL databases, NoSQL databases
    - File system
  - Storage provider (not on a server you own)
    - BLOB store
    - NoSQL databases: Next time

# Blobs: Storing uploaded files

- Example: User uploads picture
  - ... and then?
  - ... somehow process the file?

# How do we store our files?

- Dealing with text is easy - we already figured out firebase
  - Could use other databases too... but that's another class!
- But
  - What about pictures?
  - What about movies?
  - What about big huge text files?
- Aka...Binary Large OBject (BLOB)
  - Collection of binary data stored as a single entity
  - Generic terms for an entity that is array of bytes

# Working with Blobs

- Module: express-fileupload
- Simplest case: take a file, save it on the server

```
app.post('/upload', function(req, res) {
  var sampleFile;
  sampleFile = req.files.sampleFile;
  sampleFile.mv('/somewhere/on/your/server/filename.jpg', function(err) {
    if (err) {
      res.status(500).send(err);
    }
    else {
      res.send('File uploaded!');
    }
  });
});
```

- Long story... can't app.use(bodyParser) when you are handling file uploads. Instead:

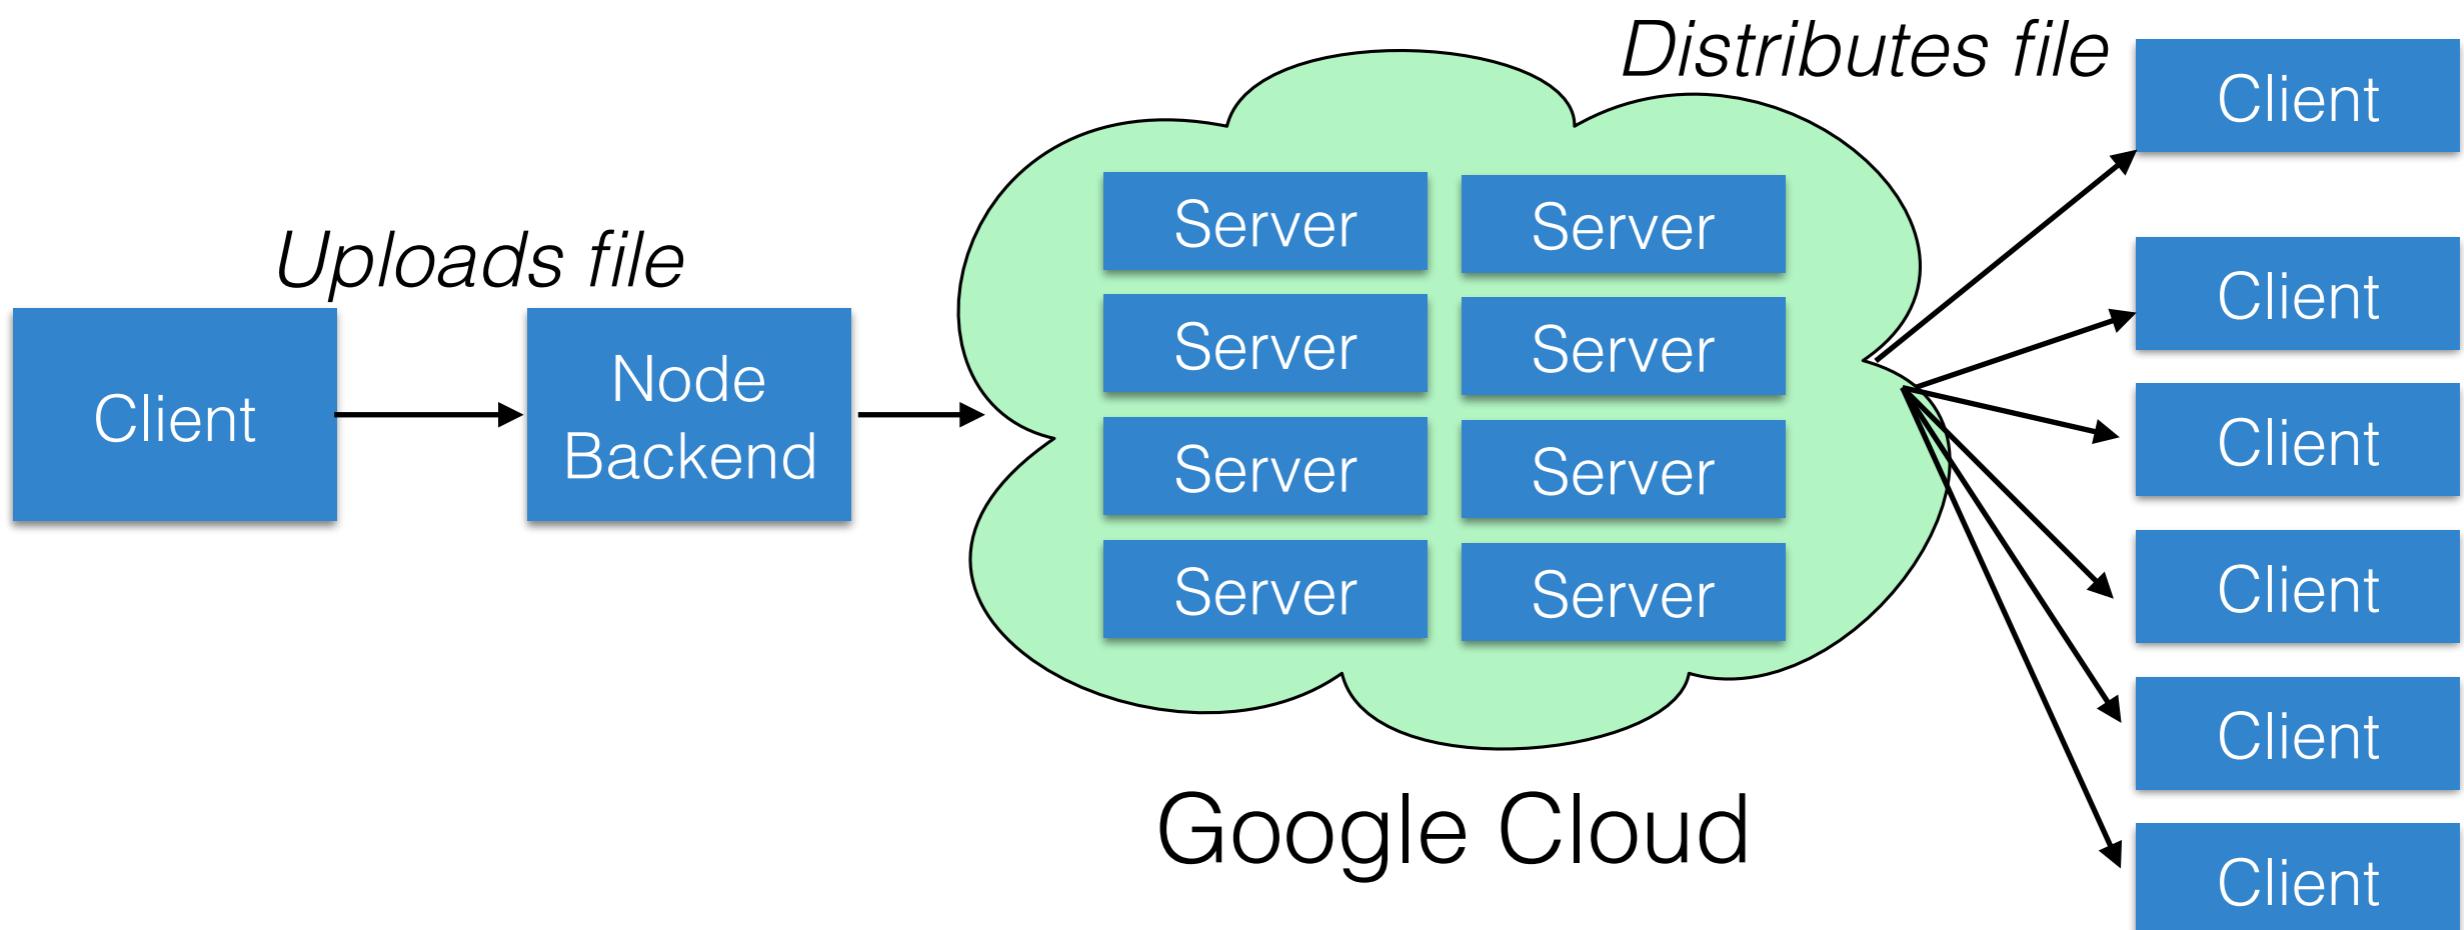

```
app.use(express.json())
  .use(express.urlencoded());
```

# Where to store blobs

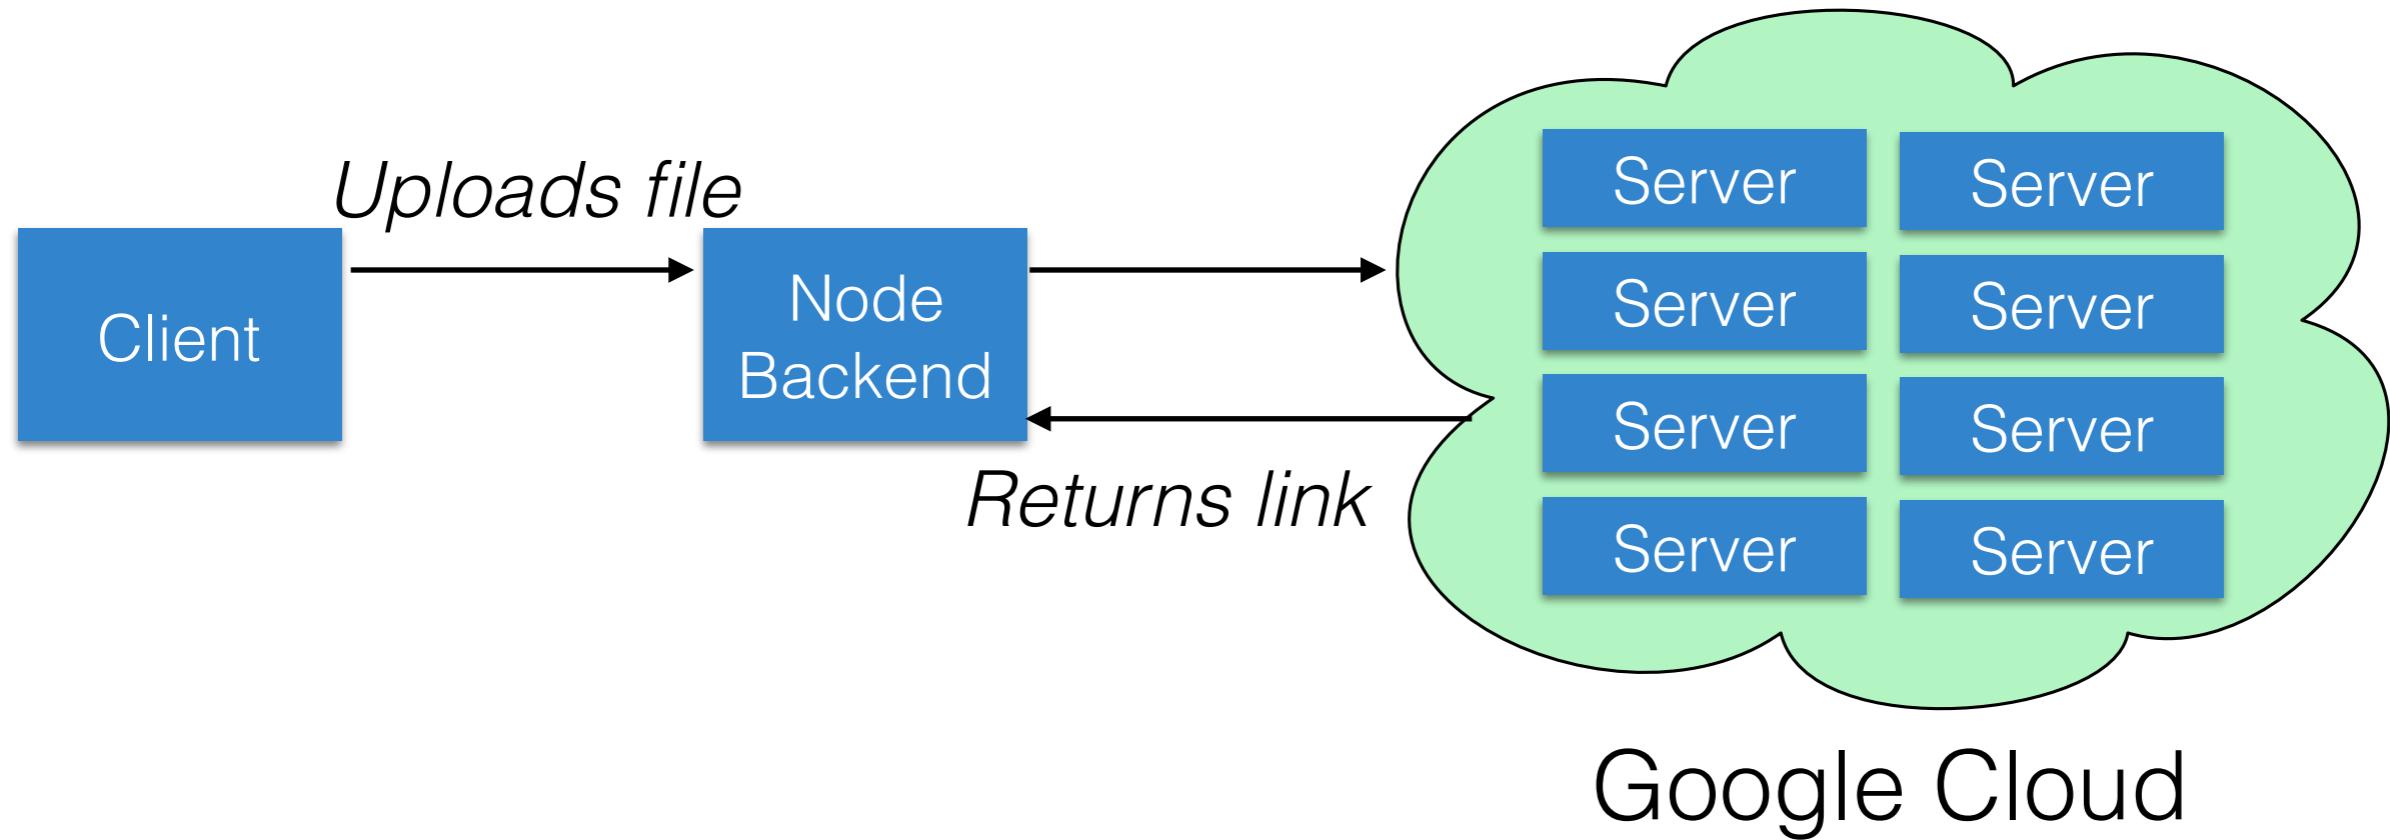

- Saving them on our server is fine, but...
  - What if we don't want to deal with making sure we have enough storage
  - What if we don't want to deal with backing up those files
  - What if our app has too many requests for one server and state needs to be shared between load-balanced servers
  - What if we want someone else to deal with administering a server

# Blob stores

- Amazon, Google, and others want to let you use their platform to solve this!

# Blob Stores

## Typical workflow:

Client uploads file to your backend

Backend persists file to blob store

Backend saves link to file, e.g. in Firebase

# Google Cloud Storage

- You get to store 5GB for free
- Setup

```
npm install --save @google-cloud/storage
```

```
var storage = require('@google-cloud/storage');

var fs = require('fs');

// Authenticating on a per-API-basis. You don't need to do this if you auth on a
// global basis (see Authentication section above).

var gcs = storage({
  projectId: 'grape-spaceship-123',
  keyFilename: '/path/to/keyfile.json'
});

// Create a new bucket.
gcs.createBucket('my-new-bucket', function(err, bucket) {
  if (!err) {
    // "my-new-bucket" was successfully created.
  }
});
```

- <https://www.npmjs.com/package/google-cloud>

# Google Cloud Storage

```
// Reference an existing bucket.  
var bucket = gcs.bucket('my-existing-bucket');  
  
// Upload a local file to a new file to be created in your bucket.  
bucket.upload('/photos/zoo/zebra.jpg', function(err, file) {  
  if (!err) {  
    // "zebra.jpg" is now in your bucket.  
  }  
});  
  
// Download a file from your bucket.  
bucket.file('giraffe.jpg').download({  
  destination: '/photos/zoo/giraffe.jpg'  
}, function(err) {});
```

# Exercise: Where to Persist

- You are building a news aggregator site and want to recommend articles based on past articles the user has clicked on. Where should you persist this?

# Exercise: Where to Persist

- You are building a shopping app and need to track a shopping card. How might you persist this?

# Where to persist application state

- Frontend
  - Data we might need to show again soon
  - Fairly small (KB's or few MBs, not 100 MB's or GB's)
  - Data we don't care about going away or being maliciously manipulated
- In memory on backend
  - Data that we are working with that will fit in memory (MB's probably not GB's)
  - Transient data that can disappear if the server crashes
  - Cache or index of data stored on backend disk, database, or storage provider
- On backend disk or database
  - Data we need persisted "permanently"
  - Data that only needs to be used by single server
- On storage provider
  - Data we need persisted "permanently"
  - Data that we need to share across multiple servers
